

Post-Catalyst Continuation Base Catalyst Database

Executive summary

I compiled a point-in-time-aware catalyst framework for systematic testing of a **post-catalyst continuation base** strategy on crypto perpetual futures, centered on assets that either had liquid perpetuals during the event window or later developed liquid perpetual markets on venues such as Binance, Bybit, Kraken, OKX, and CME/SEC-regulated channels. The working database contains **90 high/medium-confidence events** for 2020-01-01 through 2025-12-31, plus **10 excluded/noisy events** that should stay out of primary backtests. The strongest families for continuation-base testing are: **legal/regulatory overhang removal, ETF/institutional-access expansion, direct supply/float changes, and token-linked protocol utility changes**. These are the families where the mechanism plausibly persists beyond the first-event candle. Spot listings and new perpetual listings are abundant, but they are much noisier and should usually be handled as **event-day-exclusion / base-only** setups rather than breakout-chase events. ¹

The source quality is uneven by family. **Court orders, SEC filings/orders, exchange listing notices, official chain/protocol blogs, and governance proposals** are the cleanest PIT sources. **Current contract-specification pages** such as Kraken's derivatives specification page are still useful, but mainly for **effective first-trading dates** rather than first-public timestamps, so those rows should usually carry `first_public_ts_utc=unknown` and `official_confirm_ts_utc=unknown` with a note that the effective date is high-confidence but the original announcement timestamp is not recovered in this pass. ²

For C2 specifically, the most usable historical clusters are:

Family	Why it is usable for C2	Database depth
Legal/regulatory repricing	Binary overhang removal or creation often changes who can hold, list, settle, or underwrite the asset	strong
ETF/institutional access	Creates durable new demand channels and flow-sensitive post-event digestion regimes	moderate
Supply shock / unlock change	Float changes are mechanically relevant to continuation vs failure	moderate
Protocol utility / fee / revenue linkage	Best when token capture is direct, not just "good product news"	moderate
Exchange access expansion	Many events, but event-day spikes are often too crowded; best as base/reclaim-only	strong

Family	Why it is usable for C2	Database depth
Leverage access expansion	Common but ambiguous; often increases noise and short-term two-sided flow	strong
Attention-only narrative shocks	Usually too noisy unless they become a broad sector/theme repricing	weak

What should be deprioritized in primary backtests is not “weak price action in hindsight,” but **weak ex-ante mechanism clarity**: same-day meme listings, pure leverage additions with no new spot access, launchpool/airdrop events that were fully telegraphed, and social-attention bursts with no change in access, float, legal status, or token economics. That distinction matters because the C2 family is trying to isolate **post-event persistence**, not just volatility. ³

Catalyst source matrix

Source	Event types	Coverage	Timestamp quality	Free/paid	PIT confidence	Notes
SEC complaints, orders, statements	lawsuits, ETF filings/ approvals, exchange- or token-classification shocks	BTC, ETH, XRP, BNB ecosystem, SOL/ADA/ MANA/ SAND and related legal shocks	usually high on filing/order date; intraday sometimes explicit	free	very high	Best primary source for U.S. legal/ institutional catalysts. ⁴
Court orders and litigation releases	summary judgment, appeals, settlements, dismissals	XRP, Grayscale/ BTC ETF path	high on filing date; intraday often absent	free	very high	Best for legal-overhang removal events. ⁵
Binance listing and futures announcements	spot listing, deposits open, trading start, perp launch, margin expansion	very broad across mid-cap and high-beta perp universe	usually excellent; publication and effective times often explicit	free	high	Best exchange source for 2023–2025 alt catalyst history. ⁶

Source	Event types	Coverage	Timestamp quality	Free/paid	PIT confidence	Notes
Kraken derivatives contract specs	first trading dates for perps	broad alt-perp coverage, especially 2022–2025	best for effective first-trading date; poor for first-public timestamp recovery	free	medium-high	Very useful for <code>effective_ts_utc</code> , less useful for announcement timing. ²
OKX listing notices	pre-market futures, conversion-style derivatives access	selective but useful for 2024–2025 new-token discovery	good on published and effective times	free	high	Helpful for pre-market perp rows. ⁷
CME press releases	regulated futures launch	BTC/ETH institutional access pathway	high	free	very high	Important for pre-ETF institutional-access chronology. ⁸
Ethereum / BNB / protocol blogs	burns, upgrades, staking, utility changes	ETH, BNB, DYDX, AAVE, LDO, PYTH	good to excellent	free	high	Best for token-linked utility or supply changes. ⁹
Official project / governance docs	unlock schedule, staking proposals, inflation changes	ARB, OP, STRK, WLD, DYDX, AAVE	medium to high	free	high when the document is explicit	Best for float and tokenomics changes; still requires care on execution timing. ¹⁰
Telegram / World official blogs	meaningful distribution or app access changes	TON, WLD	high on announcement date	free	high	Useful when integration changes actual distribution, not just branding. ¹¹

Source	Event types	Coverage	Timestamp quality	Free/paid	PIT confidence	Notes
Reuters	fallback for widely documented but harder-to-retrieve primary court/market events	Grayscale court win, BlackRock ETF filing reaction	medium	free	medium	Good supporting source; use only when primary document retrieval is incomplete. 12

The full-schema companion files prepared in the sandbox are named `post_catalyst_c2_catalyst_db_2020_2025_main.csv` and `post_catalyst_c2_catalyst_db_2020_2025_excluded.csv`. They mirror the schema requested in the prompt and keep `unknown` where timing or impact details were not recovered at high confidence.

Main catalyst database

The full main database contains **90 high/medium-confidence rows**. To keep the report readable, the table below shows a **high-signal excerpt** across the families that matter most for C2. The companion CSV carries the full schema with fields including `known_perp_symbols`, `primary_source_url`, `supporting_source_urls`, `unknown_fields_mask`, and `notes_on_uncertainty`.

event_id	ticker	mechanism_family	mechanism_subtype	direction	event_status

CAT0099	PYTH	protocol_utility_fee_revenue_change	oracle_integrity_staking	long	confirmed

Normalization notes for the schema

Three schema conventions are worth making explicit. First, when the primary source disclosed only a filing/publication **date** but not an exact UTC time, I kept the field at date granularity rather than inventing an intraday timestamp. Second, for contract-specification pages such as Kraken's, I treated the listed **"First Trading"** date as the high-confidence `effective_ts_utc` and left `first_public_ts_utc` and `official_confirm_ts_utc` as `unknown` unless a separate launch notice was retrieved. Third, `known_perp_symbols` is intentionally partial in some rows, because the goal is not to guess every venue symbol from memory but to provide enough deterministic mapping for symbol-join work without inventing unsupported venue coverage. ²

Low-confidence and excluded events

These are not "false" events. They are events that should be excluded from the **primary** C2 backtest set because the mechanism is too weak, the catalyst is mostly attention, the event is duplicative, or the timing signal is too noisy.

event_id	ticker	exclusion reason	comment	source
CAT0076	BTC	attention-only / duplicate	"BlackRock buzz" is not a separate catalyst once the actual SEC filing is already captured.	48

event_id	ticker	exclusion reason	comment	source
CAT0012	ADA	mature-asset perp launch too weak	Kraken first-perp date is real, but novelty/demand shock is too small for primary C2 testing.	21
CAT0013	AVAX	mature-asset perp launch too weak	Same issue as ADA: legitimate event, weak ex-ante catalyst purity.	21
CAT0014	BCH	mature-asset perp launch too weak	Keep for reference, exclude from core tests.	21
CAT0033	SHIB	leverage-only on meme asset	High volatility, low mechanism clarity. Better used only in robustness checks.	19
CAT0063	PYTH	second-order margin expansion	Margin-enable events are usually too incremental relative to first spot/perp access.	32
CAT0092	SAGA	secondary-universe perp event	Valid effective date, but outside the cleanest liquid-universe priority list.	19
CAT0093	BB	secondary-universe perp event	Same reason as SAGA.	21
CAT0094	BEAM	secondary-universe perp event	Same reason as SAGA and BB.	21
CAT0020	PEPE	spot-listing mania	Keep in secondary tests if you want meme sectors, but not in a clean mechanism-first baseline.	23

The boundary here is practical. A clean C2 backtest should start with events where the market can plausibly be repricing **future access, future float, future legal constraints, or future cash-flow/usage linkage**. “Everyone noticed it at once” is not enough. 49

Backtesting plan

Ingestion and PIT handling

Store the catalyst file as an **event ledger**, not as a factor matrix. Each row should remain one event, with three timing columns kept distinct:

- first_public_ts_utc
- official_confirm_ts_utc
- effective_ts_utc

For execution logic, define the **tradable anchor timestamp** as the earliest timestamp that would have been observable to your strategy without lookahead and that still maps to a live market. In practice:

- use `first_public_ts_utc` for public filings, court rulings, and exchange announcements when time is known;
- use `official_confirm_ts_utc` when the event leaked or was rumored earlier but only became official later;
- use `effective_ts_utc` for exchange trading opens, futures-live states, hard-fork activations, unlock execution, or ETF trading launch.

If a row only has a date and no intraday time, treat it conservatively as **not tradable until the next session boundary you can implement consistently**, rather than assuming midnight UTC. This is the simplest way to avoid phantom precision and accidental lookahead. The separation is directly motivated by the disclosure patterns in SEC filings/orders, Binance notices, protocol upgrade posts, and governance/unlock docs. ⁵⁰

Joining the catalyst file to Bybit perpetual symbols

Use a symbol-resolution table with at least these columns:

asset_id	canonical_ticker	bybit_linear_symbol	first_live_ts	delist_ts	venue_aliases
----------	------------------	---------------------	---------------	-----------	---------------

The join should happen in two steps. First, map the catalyst row by `asset_id` to a canonical asset record. Second, map that asset record to the **Bybit linear USDT perpetual that was live at the event anchor timestamp**. If the Bybit contract was not yet live, either:

- drop the row from the **primary Bybit-only sample**, or
- send it to a **cross-venue validation sample** using Binance/Kraken/OKX perps or spot, depending on what was live.

That rule is especially important for spot-listing events that happened **before** Bybit had a liquid perp. Otherwise the backtest quietly turns into “would later-listed perps have reacted to a historical spot listing,” which is not a tradable PIT experiment. ⁵¹

Event families and recommended C2 test rules

These are **inference-based trading-test rules**, not historical-return labels. They are derived from the persistence logic implied by the event mechanisms above. ⁵²

Event family	Minimum wait after event	Base length to test	Hold-above-event-low rule	Exclude event-day chase	Failure-short candidate
ETF / institutional-access approval or launch	1–10 days	1–5 days for breakouts; 3–10 days for VWAP reclaims	strict	yes	yes, especially on approval-into-pre-run
Legal overhang removed	1–7 days	2–10 days	strict	yes	yes, if market loses event VWAP after day 1
Legal overhang created	0–5 days	1–5 days	inverse rule for shorts: fail-to-reclaim event VWAP	yes	primary short family
Direct supply reduction / lock-up extension	1–10 days	2–15 days	strict	yes	less often; mainly if extension was pre-run and reverses
Major unlock / float increase	0–7 days	1–7 days	for longs, only if price reclaims event VWAP after absorbing supply	yes	primary short family
Protocol utility / fee / burn / revenue linkage	1–14 days	2–15 days	strict	yes	only if token linkage proves weak and event low breaks
Major spot listing / relisting	1–5 days	1–10 days	moderate to strict	yes	yes, often one of the best failure-short families
First major perpetual listing	1–5 days	1–7 days	moderate	yes	yes; leverage events often overshoot then mean-revert

Event family	Minimum wait after event	Base length to test	Hold-above-event-low rule	Exclude event-day chase	Failure-short candidate
Pre-market futures / roadmap-to-trading transitions	1–5 days	1–7 days	moderate	yes	yes; use separate parameter set
Integration / distribution access	2–15 days	3–20 days	strict	yes	only if token-capture link is weak or largely narrative-driven

Strategy experiment design

The right benchmark is not “did catalysts go up.” It is:

1. Catalyst-base entry

2. wait for event;

3. define event high, event low, and event VWAP;

4. require post-event digestion;

5. enter only on:

- breakout from a multi-bar base above event VWAP, or
- reclaim of event VWAP after initial digestion.

6. Generic breakout control

7. same assets, same holding periods, same volatility/volume filters;

8. but without reference to catalyst dates;

9. use identical breakout and stop logic.

10. Matched non-catalyst controls

11. for each catalyst event, find non-event days in the same asset with similar realized volatility, ATR expansion, and trend status;

12. compare continuation probability after a base forms.

13. Event-family stratification

14. evaluate separately for:

- legal/ETF,
- spot listing,
- leverage listing,
- unlock/float,
- utility/revenue,
- integration/distribution.

That is the cleanest way to test whether the “base after a real repricing mechanism” adds signal beyond ordinary continuation. On the current evidence, the families most likely to survive this comparison are **legal/ETF, float change**, and the best **token-linked utility** events. Spot and perp listings will probably produce more rows, but they are exactly where you should expect the generic-breakout benchmark to catch up. ⁵³

Avoiding lookahead

Avoid lookahead in four places.

First, do not use the existence of a later Bybit perp to justify including an event that was only tradable in spot at the time. Second, do not fill in missing intraday timestamps with invented times. Third, do not use hindsight to reclassify durability based on later returns. Fourth, separate **announcement, confirmation**, and **effective** events that occur on different dates; otherwise ETF and upgrade events get compressed into one synthetic row and your backtest can enter before the market actually had access. ⁵⁴

Backtesting-agent prompt

Use the following compact prompt as the next-stage testing prompt:

You are a backtesting agent for crypto perpetual futures.

Objective:

Test a post-catalyst continuation base strategy using a point-in-time catalyst database.

Inputs:

- catalyst CSV with fields:

- event_id, asset_id, ticker, known_perp_symbols, mechanism_family,
- mechanism_subtype,
- direction, event_state, first_public_ts_utc, official_confirm_ts_utc,
- effective_ts_utc,
- source_confidence, primary_source_type, primary_source_url,
- supporting_source_urls,
- headline_raw, classification_note, durability_score_ex_ante,
- estimated_float_impact_pct,
- estimated_access_impact, pre_run_note, pre_run_risk, event_low_px_available,

- event_vwap_available, unknown_fields_mask, notes_on_uncertainty
- Bybit linear USDT perpetual OHLCV + funding + open interest if available

Rules:

- Do not use events before the relevant Bybit perp was live
- Use the earliest tradable PIT timestamp among first_public_ts_utc, official_confirm_ts_utc, and effective_ts_utc that is actually observable and not missing
- If timing is date-only, do not invent intraday precision
- Exclude low-confidence/excluded-event file from primary tests
- Do not classify event quality by hindsight return

Strategy logic:

- Define event day/session from tradable PIT timestamp
- Compute event high, event low, event VWAP
- Exclude event-day chase entries
- Only allow long continuation entries when:
 - 1) price holds above event low
 - 2) a post-event base forms
 - 3) price either breaks the base or reclaims event VWAP
- For negative catalysts, test symmetric short logic:
 - 1) price fails to reclaim event VWAP or breaks lower after base
 - 2) use event high as invalidation where appropriate

Test grid by event family:

- ETF/legal positive: wait 1-10 days, base 2-10 days
- Spot listing/relisting: wait 1-5 days, base 1-10 days
- First perp listing: wait 1-5 days, base 1-7 days
- Unlock increase: short-first family, wait 0-7 days, base 1-7 days
- Unlock delay/reduction: long family, wait 1-10 days, base 2-15 days
- Protocol utility/revenue: wait 1-14 days, base 2-15 days
- Integration/distribution: wait 2-15 days, base 3-20 days

Outputs:

- overall performance
- performance by mechanism_family and mechanism_subtype
- performance by durability_score_ex_ante
- performance by pre_run_risk
- comparison against generic non-catalyst breakout controls
- list of event families that add signal vs generic breakouts
- list of event families that are too noisy or only work as failure-shorts
- all assumptions and all dropped rows

Open questions and limitations

The strongest limitation is not event identification; it is **timestamp granularity**. Exchange announcements often provide exact times, but court rulings, governance proposals, and current contract-spec pages often do not. Those rows are still useful, but they need conservative execution rules. ⁵⁵

The second limitation is family imbalance. Exchange listings and leverage listings are abundant, while truly clean float-change and token-linked utility events are much rarer. That is a feature of the market, not a defect in the database. It means the best C2 version will likely come from **fewer, higher-quality catalyst families**, not the widest possible event count. The cleanest rows are the ones where the market had to digest a new legal reality, a new institutional access path, or a real future float change. The noisiest rows are the ones where an exchange simply turned another lever on and gave the crowd a brighter screen.
